Retained surgical gauze (Gossypiboma)

Mohamed A M Zarrouk

Zawia Teaching Hospital, Zawia University, Zawia, Libya

Abstract

Introduction: A retained surgical gauze in the abdomen is rare, underreported in the medical literature, and have catastrophic implications for patients, healthcare professionals and medical care providers.

Case presentation: A young female patient presented with abdominal swelling and pain. She has a history of a caesarian section before two months. Her radiologic investigations showed a radio-opaque marker and left intra-abdominal mass. Laparotomy done and a foreign body removed.

Conclusion: Although rare condition a gossypiboma is a complication of surgical procedure that can be prevented and modify its medico-forensic consequences.

Introduction

Retained surgical gauze (Gossypiboma) is a rare occurrence secondary to a previous open surgical procedure. The incidence in the early 1980s was varied from 1 in every 1000 to 1500 intra-abdominal operations, while more recent studies suggest an incidence of 1 in 18760 inpatient operations. It often results in adverse consequences for patients and can seriously implicate the health care personnel involved.

Case presentation

Two months after undergoing a caesarian section a 28-year-old female presented with abdominal pain and intra-abdominal swelling. There was no associated change in bowel habit. On abdominal examination, a palpable mobile tender mass in the left lumbar area was felt. Her hematological and biochemical investigations were all normal.

Ultrasonography revealed a cystic like mass with complex echogenicity. Plain abdominal radiography showed a radio-opaque marker (thread-like) figure 1. CT scanning showed a well-defined mass with air bubbles and spongiform pattern (figure 2).

Figure 1: Plain abdominal radiography showing a thread-like radio-opacity.
Figure 2: Abdominal CT scanning showing a well defined left lumbar mass with air bubbles and spongiform pattern.

At laparotomy the mass was enclosed by a thick wall attached to the posterior wall of the abdominal cavity, the wall opened and a single large surgical gauze was removed, pus cleaned and marsupialization of the wall done (figure 3). The histopathology report confirmed the absence of malignancy.

Figure 3: showing a missed surgical gauze and the removed part of the marsupialized wall.

**Discussion**

Gossypiboma is a term derived from gossypium (Latin) meaning cotton and boma a Swahili word meaning a place of concealment. It is a preventable iatrogenic complication whose delay in diagnosis and treatment can lead to a significant morbidity and mortality. It is a serious medicolegal problem, and no surgical procedure is immune to it.

There are many risk factors which can lead to gossypiboma including emergency surgery, high body mass index, intraoperative complications such as haemorrhage, abdominal and pelvic surgery, a prolonged surgical procedure, unexpected changes in a planned surgical procedure, complex surgery involving more than one team and change-over in the nursing team during surgery.

The most frequent missed foreign body was found to be laparotomic gauze.

The most common sites of gossypiboma are abdominal and pelvic cavities, followed by thoracic cavity. Gastrointestinal and gynecological operations account for about 75% of reported gossypibomas.

Retained foreign bodies (gossypibomas) induce two types of tissue reactions, the exudative reaction which presents early in the postoperative period, with
infection 2, abscess and chronic fistulae formation 4, and the other reaction is the aseptic fibrous reaction 2,4, in which the patient may remain asymptomatic for many years 2, and it may causes adhesions and encapsulation resulting in a foreign body granuloma 4.

The clinical presentation of retained foreign bodies varied 1,2,3,5, and depend on the site involved 2,5, and the type of tissue reaction elicited 2. The presentation may be acute 6 with symptoms and signs of abscess formation 1,3,4,5,6, peritonitis 3,4,6, intestinal obstruction 3,4,5,6, and abdominal pain 5, or chronic with discomfort 6, abdominal pain 1,6, mass 1,3,4,5,6, adhesions 5,6, intestinal obstruction 1,7, fistulae 5,6,8, discharging sinus 4, and transmigration of the foreign body through the hollow viscus 3,6,8, gastrointestinal hemorrhage 5, and some patients remain asymptomatic for years 3,7, and discovered incidentally during imaging study done for another reason 2.

The diagnosis can be done by the help of plain radiography 1,2,3,8, computed tomography 1,2,3,5,6,8, magnetic resonance imaging, contrast studies 2,3, and ultrasonography 1,3,5,6.

The radiological appearance of retained foreign body varies and nonspecific. It can mimic a cystic lesion 4, or it may shows a thread-like radio-opacity 8.

Diagnostic radiography can help in the diagnosis, assessment of the complications and the planning of surgery.

The treatment remain surgical removal 3 of the foreign bodies even if the patient is asymptomatic 2.

Conclusion

Gossypiboma is a rare condition but does occur after surgical operation and should be considered in the differential diagnosis of intraabdominal masses. The retention of foreign bodies in body cavities shows a weakness to be overcome and it is entirely preventable reason of morbidity and mortality. The operative team should ensure standard measures to prevent this iatrogenic complication.
